Abstract: Pediatric surgical admissions dramatically increased throughout the world as a result of increased trauma, emergency diseases and survival of congenital diseases. So, Facility based cross sectional study was conducted to identify the common pediatric (Age ≤ 15 years) surgical admissions and their outcomes at Adama Hospital Medical College. All admitted surgical patients from Jun 1, 2014 to June 30, 2015 were included in the study. Data abstraction tool was constructed to retrieve information from charts. Data was entered to SPSS version 20. Descriptive and analytic studies were performed. P value ≤ 0.05 with 95% confidence interval (CI) was used to interpret the findings. The mean age of study participants was 6 years \pm 4.5 SD. Males were 276 (71.9%) making male to female ratio of 2.5:1. Gastrointestinal conditions (33.8%) were commonest causes of admissions followed by trauma (25.5%) and congenital anomalies (19%). There were five deaths resulting in a mortality rate of 1.3%. Factors associated with death were: delay in presentation, prolonged length of stay in hospital and delay in intervention. Shorter time of presentation to intervention (< 6 hrs) was found to be significantly associated with the favorable outcomes [Adjusted Odds Ratio (AOR): 36.4, 95% CI: 3.7, 38]. Those who stayed < 7 days in the hospital were more likely to have favorable outcome (AOR: 1.7, 95% CI: 1.6, 16.8) compared to their counterparts. Delayed intervention, prolonged hospital stay and trauma are independent predictors of patient outcomes. Death in Pediatric patients with surgical conditions can be averted by avoiding these delays. Efforts to shorten length of stay in the hospital could also improve patient outcomes.

Keywords: Pediatrics, Pediatric Surgery, Outcome, Adama Hospital Medical College, Ethiopia

1. Introduction

1.1. Background

Pediatric surgical admissions dramatically increased throughout the world as a result of increased trauma, emergency diseases and survival of congenital diseases [1]. Surgical condition is any condition that requires suture, excision, manipulation or other invasive procedure that usually but not always require local, regional or general anesthesia. Surgery is often the only solution to cure or

decrease further damage, disability and death in some disease conditions. Surgical diseases are inadequately addressed globally. Both emergency and non emergency surgical conditions contribute substantially to the global burden of mortality and morbidity rates; this is even worse in low income countries [1].

Children develop distinct surgical conditions, present unique anesthetic challenges and have special preoperative need. Moreover, the consequences of pediatric surgical condition may be life long since they affect children at critical times during development. The recognition that the

surgical need of children differ from those of adults has led to remarkable improvement in care [2].

There is growing evidence that childhood surgical conditions are common in developing countries and that poor care result in significant number of deaths and disability. Unfortunately, pediatric surgical care is not considered as an essential component of most child health programmers. Even if prevention of diseases has many roles in protecting directly or indirectly acquiring congenital or non congenital disease, surgically curable disease of pediatrics also need great emphasis [2, 3].

Pediatric surgical services lack facilities and manpower often resulting in sharing wards, equipment, and nursing staffs with other surgical and even non-surgical specialties. This poses a unique challenge that influences the quality of care and outcome of children with surgical pathology in developing countries [3]. There is increasing intensity of feeling to reverse this trend, by promoting essential surgical services at the referral hospital, the first point of contact for critical conditions for rural and urban populations [4, 5].

Five-years data analyzed by Deribew M. and Adem E. at the largest university hospital in Ethiopia showed that pediatric surgical procedures accounted for 31% of all operations (N= 6070) and 33% of all pediatric admissions to the hospital [6].

1.2. Problem of Statement

Pediatric surgery has not always been considered as global health problem and health planners and implementers have not given adequate emphasis; but the global health community has recently recognized that surgical condition is significant burden of disease [7]. Surgical intervention plays a major role in preventing death and further chronic disability for those suffering from injuries, emergency abdominal and non abdominal conditions [8, 9]. Surgery is at the end of the spectrum of the classic curative and preventive medical model [10]. Surgical conditions had been accounted for significant portion of population's disease burden particularly in developing countries where conservative treatment is not readily available [11].

Globally, approximately 28% of global burden of diseases were amenable to surgical interventions; around half of them were pediatric surgical pathologies. In the Sub-Saharan Africa, the annual presentation rate for all surgical conditions was 543 per 10000 children age 0 -14 years. The estimated cumulative risk for all surgical conditions was 85.4% by the age of 15 years [10, 11].

Out of 234 millions of surgical procedures performed worldwide, only 3.5% were performed in poorest nations (including Africa) [12, 13]. Increasing access to surgery and quality of surgical intervention may help to achieve healthy and more productive generations and as well to reduce the potential pediatric age mortality rate [14].

Data are lacking on the spectrum of surgical conditions on the mortality and morbidity associated with lack of surgical services and the burden of pediatric surgical diseases on the health systems [8]. Incomplete information has made it

difficult to define an appropriate role for pediatric surgery in Africa, and to assess the impact of surgical diseases on children health [1].

2. Methods and Materials

2.1. Study Area and Period

The study was conducted in Adama hospital medical college, which is located in Adama town, Oromia Regional State, Ethiopia. The hospital is a teaching referral hospital staffed with five Pediatricians and four Surgeons. There are 75 pediatric beds; 15 beds are dedicated to surgical and orthopedic patients. This study was conducted with the aim of determining the pattern of pediatric surgical admissions and its outcome in Adama hospital medical college from Jun 1, 2014 to Jun 30, 2015.

2.2. Study Design

Hospital based cross-sectional study design was employed from June 1, 2014 to Jun 30, 2015. All admissions with complete data were included. The data was entered into SPSS version 20 for analysis. Descriptive and analytic statistical methods were utilized. P value <0.05 was considered as statistically significant with 95% CI.

3. Results

3.1. Socio-Demographic Characteristics

The mean age of the study participants was 6.09 (SD ±4.6) years. Male to female ratio was found to be 2.5:1. Nearly 21% of the participants were under one year of age. 71.1% (N=273) of the study units were from rural parts of the region (Table 1).

Table 1. Socio- demographic characteristics of admitted pediatric surgical patients, at AHMC, Jun 1, 2014 – June 30, 2015.

Variables	Category	Numbers	Percent
Sex	Male	276	71.9
	Female	108	28.1
Age	< 1 years	82	21.4
	1-4 years	90	23.4
	5-9 years	129	33.6
	10-14.9 years	83	21.6
Residence	Rural	273	71.1
	Urban	111	28.9

3.2. Patterns of Pediatric Surgical Admissions and Its Outcomes

Eighty two percent of the admissions were on the emergency bases. The commonest causes of surgical admissions were gastrointestinal conditions (33.8%, N=130), trauma (25.5%, N=98) and congenital anomalies (19%, N=73). From gastrointestinal conditions, appendicitis (54%, N=70) and intestinal obstruction (30%, N=39) were the commonest diagnoses observed (Table 2).

Scald and flame burn were the major (85%) causes of

burn injury. Fall down injury and road traffic accidents constitute 88% of all fractures. The most common congenital anomalies were inguinal hernia (38.4%) and undescended tests (16.4%). The most common surgical site infections were any space occupying abscesses (47%) and osteomyelitis (25%) (Figure 1).

The mean duration of hospitalization was 6.22 days (SD \pm 5 days). Minor and major operations accounted for 69.3% (N=266) while conservative management (orthopedic application, wound care and medication) accounted for

30.7% (N=118). Unfavorable management outcome occurred in around 19% (N=69) of cases where Surgical Site Infection (SSI) accounts for nearly 93%.

There were 5 deaths giving an overall mortality rate of 1.3%. Complicated intestinal obstructions and congenital anomalies accounted for 80% (N=4) of death. Twenty nine (7.5%) of admitted patients were referred out to other health institution either for lack of services or self referral. The referred out cases were either congenital anomalies 13 (44.8%), burns 14 (48.3%) or head injuries.

Table 2. Distribution of study subjects according to their patterns of surgical admissions and its outcomes at AHMC from Jun 1, 2014 to Jun 30, 2015.

Variable	Response category	Number	percent
Condition at admission	Emergency	315	82
	Elective	69	18
	Congenital anomaly	73	19
Diagnosis during admission (N=384)	Trauma	98	25.5
	Surgical infection	64	16.6
	Gastrointestinal problems	130	33.8
	Others*	19	5.1
	Inguinal hernia	28	38.4
Congenital anomalies (n=73)	Club foot	11	15.1
	Undescended tests	12	16.4
	Duodenal atresia	5	6.8
	Others**	10	10.9
	Osteomyelitis	16	25
Surgical site infections (SSI) (n=64)	Any space occupying abscesses	30	47
	Cellulites	11	17.2
	Septic arthritis	7	11
	Intestinal obstruction	39	30
Gastrointestinal problems (n=130)	Appendicitis	70	54
	Pyloric stenosis	13	10
	Others***	8	6
	Favorable outcome	286	80.5
Outcome of surgical admission (N=355)	Un favorable outcome	69	19.4

3.3. Determinants of Factors Associated with Outcomes of Pediatric Surgical Admissions

With binary logistic regression urban residents, duration of onset of symptoms <24 hours and short lengths of stay in the hospital were predictors of favorable outcomes. However; age, sex and causes of surgical admissions were not associated with outcome of the interventions ($p > 0.05$). Those coming from the urban areas were more likely to have favorable outcome compared to their counterparts [Crude Odds Ratio (COR): 2.96, 95% CI: (1.76, 4.98)]. But, after adjusting for other variables it was not found to be significant [AOR: 1.47, 95% CI: (0.23, 9.6)]. The time of presentation to

intervention (< 6 hrs) was found to be significantly associated with the favorable outcome [AOR: 36.4, 95% CI: (3.7, 38)]. Those who stayed < 7 days in the hospital were also significantly associated with favorable outcome [AOR: 1.7, 95% CI: (1.6, 16.8)]. Those who had < 24 hours of onset of symptoms were significantly associated with favorable outcome compared to the reference category [COR: 7.73, 95% CI (4.65, 12.8)], but not significant after adjusting for other variables [AOR: 0.52, 95% CI (0.86, 51.8)]. Trauma was significantly associated with favorable outcome [AOR: 20.4, 95% CI (1.99, 25.5)] compared to other causes of admissions.

Table 3. Factors associated with outcomes of pediatric surgical admissions.

Variables	Outcomes of pediatric surgical admissions		COR(95%CI)	AOR (95%CI)
	Unfavorable	Favorable		
Time before intervention				
<6 hrs	24(24.5%)	221(77.3%)	10.48 (6.13,18) **	8.00 (3.70,13.00) *
≥6 hrs	74(75.5%)	65(22.7%)	1.00	1.00
Length of hospital stay				
<7 days	43(44%)	251(88%)	9.2(5.4,12.2)**	1.7(1.6,16.8)*
≥7 days	55(56%)	35(12%)	1.00	1.00
Duration of symptoms				
<24 hrs	35(36%)	232(81%)	0.73(4.65,12857)*	0.52 (0.86,51.80)
≥24 hrs	63(64%)	54(19%)	1.00	1.00
Area of residency				
Urban	23(23.4%)	136(47.5)	2.96(1.76,4.98)**	1.47(0.023,9.635)
Rural	73(74.5%)	150(52.4)	1.00	1.00
Case type

Non-trauma	64(77.1%)	139(61%)	1.00	1.00

NB *p-value<0.05, **p-value<0.001

4. Discussion

Boys are more affected than girls even if it is not statistically significant. The studies done in Ethiopian and Nigerian tertiary hospitals also showed the same finding. This could be explained partly by males being more predisposed to both gastrointestinal problems and trauma [6, 8]. The three most common causes of admissions (gastrointestinal problems, trauma and congenital anomalies) in this study were also found by other similar studies [4, 6].

Burn and fracture cases constitute the leading causes of trauma. Scald and flame burns are the commonest types (85%) of burn cases while fall down and road traffic accidents constitute the major (88%) causes of fracture. This is in line with the study done by Simmons D. where 27% and 32% of accidents were caused by scald burns and fractures respectively [15]. The common cause of fracture in Simmons's study was fall accident while it is road traffic accident in our study. This could be because Adama town is found on the high traffic corridor of the country [16].

From congenital anomalies, inguinal hernias are the

most common encounters. This is similar to different studies conducted in Africa [4, 9]. But, the second most common congenital malformation in these studies, meningomyelocele, was not encountered likely because these malformations are referred to other centers.

In this study, unfavorable outcomes (death or surgical site infection) rate was 19.4%. This result is lower than the study done in Nigeria where a total of 56 patients were operated for intussusceptions at Buganda Medical Centre and 37.5% of them developed surgical site infection (the most frequent complication in the study) [17]. Death was observed in 1.3% of cases. It is slightly lower than the study by Osifo OD and Aduwa IP where 3% mortality rate was reported [8]. But it is much lower than the 7.46% reported mortality rate from a study in a zonal hospital (Yirgalem) in the same country to this study. The smaller sample size in this study (N=134) might have affected the result [18].

Duration of symptoms at presentation (dichotomized at 24 hours) and area of residency (rural/urban) were only statistically significant by bivariate logistic regression. Independent predictors of unfavorable outcomes were length of hospitalization for > 7 days, the time of

presentation to intervention (> 6 hrs) and trauma patients. The study done by Osifo AD and Aduwa IP at Buganda Medical Centre also showed that delayed presentation and associated surgical site infections were predictors of mortality in admitted pediatric surgical patients [8].

5. Conclusion

The common causes of admissions into pediatric surgical wards at the study site are gastrointestinal conditions, trauma and congenital anomalies.

SSI is very high in our study. Even if it is not direct predictor of patients' outcome in our study, clearly it will contribute to prolonged length of hospitalization. Delayed time of intervention of more than six hours, prolonged time of hospitalization for more than seven days and trauma are independent predictors of patient outcomes. Death in Pediatric patients with surgical conditions can be averted by avoiding these delays. Effort should be made to minimize the rate of surgical site infections. Reasons and ways to decrease length of hospital stay must be sought.
