Abstract: Background: Healthcare providers are engaged in providing patient care and may expose to COVID-19 during their work, Understanding the psychological impact of the COVID-19 among health care providers is important in facing the pandemic. Objective: We examined the psychological distress, depression, anxiety, and stress among healthcare providers during the COVID-19 Pandemic in Gaza Strip. Methods: The descriptive design was used, 231 health care providers for corona patients were selected purposively, Depression, Anxiety, and Stress Scales (DASS-21) In addition to information on demographic characteristics was used in this study. Results: The mean weight for depression domain 68% and the mean weight for anxiety 69%, on the other hand, the mean weight for stress 67%, the study show that Mean Rank and the p-value equal 0.693, which is greater than 0.05, which means there are no significant differences between psychological distresses due to gender among healthcare providers during the Covid-19 pandemic, the study found that the p-value <0.05, which means there are significant differences between psychological distresses due to years of experience in favor of more than 12 years and type of job in favor of Nonmedical Health Care Personnel. Conclusion: Our study highlights that nonmedical health care personnel are at the highest risk for psychological distress during the COVID-19 pandemic.

Keywords: COVID-19, Psychological Distress, Health Providers

1. Introduction

The coronavirus COVID-19 pandemic has become a global health crisis that significantly affects the international health system across the world. Since the start of the Corona pandemic globally, all travelers coming through Rafah and Beit Hanon (Erez) crossings had undergone a compulsory quarantine at one of the Ministry of Health (MOH) designated facilities, isolation hospitals, and health quarantine centers. People stay for 21 days in quarantine centers, health services are provided, and laboratory tests are

carried out by the medical staff present with them around the clock, according to the MOH, the number of service providers in the quarantine centers reached 389 employees, 20% are a medical team, On 26 August 2020, MOH in Gaza confirmed the first COVID-19 spread through the community in the Gaza strip. When preparing this study, the total number of confirmed cases is 53440, of which 2949 are still active cases, 49955 cases fully recovered and were discharged, while the number of deaths reached 536 deaths [1].

Healthcare providers are engaged in providing patient care and may expose to COVID-19 during their work. Moreover, they are not only at risk for physical challenges but also mental

burdens, particularly psychological distress [2]. Healthcare workers are facing unprecedented amounts of COVID-19-related psychological stress across professional and personal domains [3]. The adverse psychological impact includes acute stress disorder, insomnia, post-traumatic symptoms, and depression [4]. The unusual circumstances in which the medical team works and their presence in the same place for 21 days with people infected with or suspected of being infected with the virus in addition to their anxiety for themselves and their families, these factors considers sources of anxiety, stress, and depression for health care providers. COVID-19 has resulted in high levels of uncertainty, anxiety, social isolation, and further inequity in health care for Palestinians in Gaza [5]. World Health Organization (WHO) issued a COVID-19 guideline on mental health and psychological distress to support people's mental and psychological wellbeing during this outbreak [6]. Moreover, we mean here by psychological distress that it includes the emotional state of depression, anxiety, and stress. Anxiety is defined as irrational and excessive fear, apprehensive, and tense feelings difficulty managing daily tasks, and/or distress related to these tasks [7]. People with experience a range of symptoms including persistent depressed mood or loss of interest and pleasure for at least 2 weeks suffer from depression [8]. Hans Selye defines stress as the "perception of threat, with resulting anxiety discomfort, emotional tension, and difficulty in adjustment." [9]. The present study will provide recommendations to deal with psychological problems during the COVID-19 pandemic and improve the mental health status among healthcare providers. This study aims to assess the level

of the emotional state of depression, anxiety, and stress among health care providers during the COVID-19 in Gaza Strip.

2. Methodology

2.1. Study Design

The design of this study cross sectional design.

2.2. The Study Population

Health care providers working with covid 19 infected patients (physicians, Nurses, Nonmedical Health Care Personnel)

2.3. Sample

The sample consists of 231 healthcare providers for Covid 19 patients who work at the Turkish Friendship Hospital and the European Gaza Hospital. The type of sample is purposive sample (Non-probability).

2.4. Instruments

Validated Depression, Anxiety, and Stress Scales (DASS-21) In addition to information on demographic characteristics [10].

2.5. Procedure

From 15 August to 20 October 2020, health care workers from 2 major hospitals in Gaza who were caring for patients with COVID-19 were invited to participate with a self-administered questionnaire (online).

3. Results

3.1. Level of Depression, Anxiety, and Stress Among Healthcare Providers During the COVID-19 Pandemic in Gaza Strip

Table 1. Description of respondents' psychological distress (n = 231).

Weight mean %	Mean	Very severe	Severe	Moderate	Mild	Normal	scale
68%	2.0433	162	8	20	22	19	Depression
69%	2.0816	174	11	27	10	9	Anxiety
67%	2.0198	129	36	5	11	50	Stress

Table 1 shows that the level of depression, anxiety, and stress among health care providers during the COVID-19 Pandemic. In the depression domain, 19 participants are normal degrees, 22 from participants were mild degrees and 20 were moderate while 8 participant's severe degrees and 162 were very severed. The level of depression on the whole depression scale equals 68%. On other hand, in the anxiety domain, 9 participants were normal

degree, 10 participants were mild degree and 27 were moderate, 11 were severe degree, while 174 participants were a very severe degree. The level of anxiety on the whole anxiety scale equals 69%. In contrast, in the stress domain, 50 participants were normal degree, 11 participants were mild degree and 5 moderate degrees, 36 participants severe while 129 were very severed. The level of stress on the whole stress scale equals 67%.

3.2. The Relationship Between Depression, Anxiety, and Stress Level Due to Gender Among Healthcare Providers During the COVID-19 Pandemic in Gaza Strip

Table 2. Mann-Whitney test to view up the relationship between psychological distresses due to gender among healthcare providers during the Covid-19 pandemic.

items	Gender	N	Mean Rank	Sum of Ranks	Z	p-value
Psychological distress	Male	150	114.73	17209.00	-0.395	0.693
	Female	81	118.36	9587.00		
	Total	231				

*P < 0.05

Table 2 shows that Mean Rank and the p-value equal 0.693, which is greater than 0.05, which means there are no significant differences between psychological distresses due to gender among healthcare providers during the Covid-19 pandemic

3.3. The Relationship Between Depression, Anxiety, and Stress Due to Years of Experiences Among Health Providers During the COVID-19 Pandemic in Gaza Strip

Table 3. Kruskal-Wallis test to view up the relationship between psychological distresses due to years of experiences among healthcare providers during the Covid-19 pandemic.

Items	experience	N	Mean Rank	df	p-value
Psychological distress	below 5 years	84	121.76	2	0.02*
	5-12 years	75	99.40		
	up 12 years	72	126.57		
	Total	231			

P < 0.05

Table 3 shows the relationship between psychological distresses due to years of experiences by using the Kruskal-Wallis test. The p- values are less than 0.05 in psychological distress scores, thus there is a significant relationship

between psychological distresses due to years of experiences in favor of more than 12 years' experience among healthcare providers during the COVID-19 pandemic.

3.4. The Relationship Between Psychological Distresses and Type of Occupation Among Health Providers During the COVID-19 Pandemic in Gaza Strip

Table 4. Kruskal-Wallis test to view up the relationship between psychological distresses levels due to type of occupation of healthcare providers during the Covid-19 pandemic.

Item	Professions	N	Mean Rank	df	P-value
Psychological distress	Nurse	152	105.41	2	0.003*
	Doctor	27	127.87		
	Nonmedical Health Care Personnel	52	140.78		
	Total	231			

* P < 0.05

Table 4 shows that the relationship between psychological distress due to occupation by using K independent variables test. The p- values are less than 0.05, which means there is a significant difference between psychological distresses to occupation in favor of Nonmedical Health Care Personnel as (administrators, maintenance workers).

4. Discussion

Overall mean DASS-21 among health care workers were higher than those in the published previous studies as [2, 11, 12] which showed that an almost 2 times lower level of DASS-21, than those in our study. This could be attributed to in addition to the risks of infection from Corona and work stress, health care providers suffer from difficult economic, social, and political conditions such as low salary, lack of human staff, sieges and wars, all these factors and others, in addition to the Corona pandemic, have contributed to the increase of severe symptoms in levels of depression, anxiety and stress among health care providers. Our study agree with study 46.5% were mild to moderately distressed and 6.7% were severely distressed due to the current COVID-19 pandemic [13]. The prevalence of mild distress was reported to be lower among health workers from China (36.5%) [14] and in Saudi Arabia (33.7%) [15] as compared to the findings of our study.

The present study show that there are no significant differences between psychological distresses due to gender among healthcare providers during the Covid-19 pandemic, this result disagrees with another study[11] which show that the largest distress burden falls on females relative to males.

On other hand, the study found that there are significant differences between psychological distresses due to years of experience in favor of more than 12 years and type of job in favor of Nonmedical Health Care Personnel. This result agree with other study [2, 12]. Reasons for this may include increase in working years with the continuing difficult working conditions and sources of stress, in addition to the Corona pandemic, leads to the person being exposed to severe levels of anxiety, depression and stress, On the other hand, Nonmedical Health Care Personnel are less information on the corona, less intensive training on personal protective equipment and infection control measures. In addition, Nonmedical Health Care Personnel are not included in the psychological support that targets medical teams only.

As the pandemic continues, psychosocial intervention program are needed to support health care providers, our study identified vulnerable groups who are more at risk to psychological distress. Self-care program and educational intervention should target nonmedical health care personnel to increase their awareness about mental health.

The study suggests activating a face-to-face psychological

counseling service or by calling to support medical and non-medical health care personnel in facing the pandemic, teaching them positive coping methods, and providing useful psychological advice and guidance to them to reduce the level of depression, anxiety and stress.

5. Conclusion

Our study highlights that nonmedical health care personnel are at the highest risk for psychological distress during the COVID-19 pandemic. This study emphasizes the need to pay attention not only to people but also to health care providers during the COVID-19 pandemic. We hope that this descriptive study will contribute to understanding how the COVID-19 pandemic affect mental health among health care providers. Early psychological interventions like helping the helpers program targeting this vulnerable group may be beneficial and important to provide counseling and psychological support to them when needed so that they are able to cope with stress and life problems.
