Received: March 13, 2020; **Accepted:** April 2, 2020; **Published:** May 27, 2020

Abstract: Water, potential source of life, must undergo various physico-chemical and bacteriological analyzes that will define its quality for human consumption in order to avoid the risk of water-borne diseases to consumers. Physico-chemical and bacteriological quality of an Ouéga-Fandji's drilling water, use as drinking water, were investigated. Two (02) samples are constituted for the two analyzes' types. Twenty physico-chemical parameters (pH, Temperature, Electrical conductivity, Colour, Turbidity, Nitrites, Nitrates, Ammonium, Calcium, Magnesium, Total iron, Bicarbonates, Alkalinity, Chlorides, Sulphates, Fluorides, Iodides, Total hardness, Total Dissolved Solids) and three bacteriological parameters (Fecal coliforms, Total coliforms, Fecal streptococci) are evaluated on samples. Some physical parameters (temperature, pH, turbidity and conductivity) able to change during transport have been determined "in situ" using a portable multimeter (HANNA, HI 991300). The results obtained showed that unwanted substances (nitrites, nitrates, ammonium, fluorides, sulfates and iron) were almost absent. The physico-chemical parameters measured in this water sample comply with the quality standards for drinking water in Benin Republic. The conclusion is the same for bacteriological parameters, although the number of total coliforms (13 CFU) present in 100 mL of this water sample exceeds that recommended in Benin Republic. Therefore, disinfection of this water by the usual disinfection methods like chlorination with calcium hypochlorite is mandatory.

Keywords: Drilling, Drinking Water, Physico-chemical, Bacteriological

1. Introduction

Water, a potential life source, is one of the drivers of the organization and development of territories [1]. Unevenly distributed over the earth and present in sometimes limited quantities, it constitutes a major environmental issue [2]. The lack of sanitation infrastructure (presence of garbage dumps, latrines and not waterproof septic tanks) and the mismatch of the rainwater and wastewater disposal system make run a significant risk of contamination to aquifers. Also, the groundwater supply proceeds by vertical infiltrations of runoff from precipitation, and surface waters' infiltrations. The risks of their chemical and biological pollution depend on the one hand, on seepage water characteristics, and on the other hand, on the natural properties of the geological layers

which separate the water table from the soil surface [3]. Therefore, water that is a life's source becomes disease source [4]. In developing countries, obtaining safe water for human consumption has become a serious problem due to an environmental protection lack [5]. Many parts of the world depend entirely on groundwater resources for various uses. Groundwater contaminated with various pollutants which make it unfit for consumption can endanger human and animal life as well as the environment as a whole. Specific concrete actions are therefore necessary to control the risk of water pollution and protect the natural quality of groundwater [6]. The problem related to the supply of drinking water is a key issue for African countries in general and those of West Africa in particular [7]. In Benin, almost a third of households use raining water as drinking water. 22.6% of

households obtain water from unprotected wells and river water (13.2%) which are sources of non-potable water. Households also are sourcing water fountain (21.2%) and water from protected well (8.3%) [8]. The non-permanent supply of drinking water by the national distribution network (SONEB) has led people to resort to ground and surface water. The chemical composition of water from the natural environment is very variable. It depends on the geological nature of the soil where it comes from and the reactive substances it encountered during the flow [9]. Degradation of groundwater resources has become a global concern in these last decades [10]. Groundwater has traditionally been the privileged water resource for drinking water production, as it's less vulnerable to pollution than surface water. Nevertheless, some minimum characteristics are required for them to be able to be used as drinking water. Drinking water must meet physico-chemical and biological quality standards [4]. The natural quality of the groundwater can be altered by anthropogenic activities or natural phenomena. In addition, apart from fresh water availability and associated anthropogenic factors, transport and storage significantly influence the quality of drinking water. The degree of quality required for water obviously depends on its use [11-12]. Abomey-Calavi's commune is one of the areas least served by the National Water Company of Benin (SONEB). Populations use water from drillings and wells without analysis. Therefore, many studies [13] were carried out on the quality of drilling or well water in Abomey-Calavi's commune and have shown that it's unfit for human consumption. There is few occurrences in literature of the assessment of Ouéga-Fandji's drilling water. The aim of this paper is to investigate the physico-chemical and bacteriological quality of this water.

2. Material and Methods

2.1. Study Areas

The water samples used for physico-chemical and bacteriological analysis was collected in "Ouéga Fandji" in Togba district at Abomey-Calavi's commune. The commune of Abomey-Calavi is a bar land's area, located in the Atlantic department in south of Benin between 6°26'54" North latitude and 2°21'20" East longitude [14].

2.2. Sampling and Analysis

The samples were taken in 0.5 L glass bottles with caps wrapped in aluminum paper and then sent to the laboratory for analysis. However, pH, conductivity, TDS and temperature were measured "in situ" using a portable multimeter (HANNA, HI 991300). Bicarbonates, chlorides, calcium, magnesium and total hardness were measured by titrimetry while ammonium, color, total iron, iodides, nitrates, nitrites, sulfates and fluorides were determined by a spectrophotometer of HACH DR/2400 type in accordance with the analysis methods of the French Association for Standardization, AFNOR [15-16]. Fecal streptococci, fecal

coliforms and total coliforms were the main microbiological parameters sought. These germs were determined by the membrane filtration method as described in [16]. This method is widely used for the enumeration of microorganism germs in water intended for human consumption.

3. Results and Discussion

3.1. Physical Parameters

Physical parameters such as pH, electrical conductivity, temperature, color and turbidity presented the results in Table 1. The pH of the water analyzed is 7.02. This pH value is well within the allowed pH range of 6.5 - 8.5. The temperature of a water plays a determining role in the modification of the physical and chemical properties of water. Indeed, it influences its density, the solubility of gases, the dissociation of dissolved salts, the biochemical and biological reactions that occur in water [17]. The temperature of 26.7 °C obtained is slightly higher than the standard. This could be attributed to the fact that the water temperature depends on the time of its withdrawal and is intimately linked to the ambient temperature at withdrawal time [1]. Water temperature has no direct impact on human health. However, a high temperature (above 20 °C), like that of the waters studied, promotes microorganisms development [18]. The analysis of water color shows that the water isn't very colored with 01 CU for color value. It meets the maximum standard required which is 15 CU. The color value obtained is lower than those obtained in [19]. Their investigations on well water in Congo Brazzaville revealed color values between 7 and 10. The established turbidity standard is 5 NTU. The water sample analyzed showed no turbidity. This turbidity obtained meets the required standard and is identical to that in our investigations into drinking water of Dassa - Zoume [1]. The electrical conductivity reflects the degree of overall mineralization. It informs about the salinity rate [20]. The conductivity of water is the measure of its ability to conduct electrical current. It varies with temperature and is related to the concentration and nature of the dissolved substances (TDS) in the sample [21]. In fact, the higher the conductivity, more strongly the water is mineralized. The electrical conductivity of 33 $\mu\text{S}/\text{cm}$ obtained is below maximum standard (2000 $\mu\text{S}/\text{cm}$). This conductivity result is close to those obtained in [22] on well water from Lagos in Nigeria with conductivity values between 22 and 315 $\mu\text{S}/\text{cm}$. However, this result is contrary to those in [23]. They obtained conductivities higher than the norm in the wells of Lome in Togo.

Table 1. Physical parameters of drinking water.

Parameters	Values	Benin Standards
pH	7.02	6.5 – 8.5
Temperature (°C)	26.7	≈ 25
Electrical conductivity ($\mu\text{S}/\text{cm}$)	33	2000
Color (CU)	01	15
Turbidity (NTU)	00	≥ 5

3.2. Chemical Parameters

3.2.1. Nitrogenous Mineral Compounds

The nitrogenous mineral compounds investigated revealed very small quantities (Table 2). It confirms the good quality of this water. Unwanted substances (nitrites, nitrates, ammonium, fluorides, sulfates and iron) were almost absent. The enrichment of water in nitrates results from diffuse pollution linked to the percolation of rainwater from cultivated soils and to point pollution caused by direct infiltration of wastewater. In general, the presence of nitrates "very soluble in water" comes from agriculture, discharges from local communities and industry. Nitrates are today the major cause of groundwater pollution [24]. The low quantities of nitrogen and phosphate mineral compounds previously obtained from the water distributed by SONEB confirmed the good quality of this water [1].

Table 2. Characteristic parameters of nitrogen in drinking water.

Nitrogen	Content (mg/L)	Standards in Benin
Nitrous (NO ₂ ⁻)	0.0	0.1
Nitric (NO ₃ ⁻)	0.18	45
Ammonia (NH ₄ ⁺)	0.0	0.5

3.2.2. Other Physico-Chemical Analysis

Table 3 presents the results of some physico-chemical analysis carried out on the water sample taken. This sample contains dissolved ions, the main ones being calcium, magnesium and bicarbonates. These ions essentially come from soils' leaching by rainwaters. Their content depends directly on rocks' nature [24]. The results show that the essential substances (calcium, magnesium) are generally in low concentrations respectively 0.8016 mg/L and 0.7296 mg/L compared to the accepted standards. The hardness of a water is linked to the geological nature of the terrain crossed and reflects its content of calcium and magnesium salts. It results in precipitation of the scum of the soap or its excessive use during cleaning activities [25]. The sample had a total hardness of 5 mg/L, 100 times lower than the standard (500 mg/L). The alkalinity value obtained is 10 mg/L. Indeed, bicarbonates constitute the main part of the water alkalinity observed. They can come from the dissolution of carbonate formations depending on the reaction: $\text{CaCO}_3 + \text{H}_2\text{O} \rightarrow 2\text{HCO}_3^- + \text{Ca}^{2+}$ [29]. According to [25], carbon dioxide (CO₂) present in the soil or in the atmosphere is the main source of alkalinity in groundwater or surface water. The analysis revealed a concentration of iodides of 0.04 mg/L. Iodine is a mineral and a trace element, the deficiency of which leads to disturbances that cause brain damage, cretinism, and lead to miscarriages, reduced fertility and goiter. These disorders constitute the most important cause of mental retardation and also the easiest to prevent [1]. Total dissolved solids (TDS) report the mineral amount in the water. The concentration of TDS in water varies considerably in different geological regions due to the difference in solubility of minerals [26]. The dissolved solids (TDS) content expresses the total concentration of dissolved substances in water. TDS is composed of inorganic salts and

some organic matter [21]. The water analyzed presented a TDS of 33, a value below the required standard. In general, the investigated drinking water presented a physico-chemical quality in accordance with Benin standards.

Table 3. Some physico-chemical parameters of drinking water.

Parameters	Contents (mg/L)	Benin Standards
Calcium (Ca ²⁺)	0.80	100
Magnesium (Mg ²⁺)	0.73	50
Iron (Total iron)	0.08	0.3
Bicarbonates (HCO ₃ ⁻)	6.1	-
Alkalinity in CaCO ₃	10	-
Chlorides (Cl ⁻)	0	250
Sulfates (SO ₄ ²⁻)	0	500
Fluorides (F ⁻)	0.0	1.5
Iodides (I ⁻)	0.04	-
Total hardness	05	500
TDS	33	2000

TDS: Total Dissolved Solids

3.3. Bacteriological Parameters

Table 4 presents the results of the bacteriological tests carried out on the water sample taken. Bacteriologically, the water has been found to be contaminated with total coliforms. The other two germs (Fecal coliforms and Fecal streptococci) are not detected there. The standards require the total absence of germs indicating fecal contamination in water intended for human consumption [20]. This is observed in the sample studied. The presence of total coliforms doesn't constitute an immediate health risk (quality standards for drinking water in Benin Republic 2001) [21]. So therefore, the bacteriological quality degree of this water is acceptable. However, the number of total coliforms present in this sample exceeds that recommended by the quality standards for drinking water in the Republic of Benin. It is therefore important to disinfect this water by the usual methods of disinfection as chlorination based on calcium hypochlorite or sometimes with bleach, the active ingredient of which is sodium hypochlorite. The investigations on the bacteriological quality of water of well and drilling have done in Lome. Analyzed drilling water is less contaminated compared to wells' water because of the difference between the depth of wells and that of drilling [27]. Indeed, boreholes in Lome are carried out in neighborhoods where it is more difficult for residents to make wide diameter wells. Because of the relief and the nature (sandy clay) of the soil, access to water in this area is through drilling at depths that go on average beyond 30 meters [27]. This observation is frequent in this study area. Furthermore, The investigations into groundwater had shown that the boreholes in the city of Bembèrèkè have acceptable bacteriological quality [28].

Table 4. Bacteriological parameters of drinking water.

Parameters	Values in 100 mL	Standards in Benin
Fecal coliforms	13	10
Total coliforms	0	0
Fecal streptococci	0	0

4. Conclusion

The physicochemical parameters measured in this drinking water sample comply with the quality standards of drinking water in the Republic of Benin. From microbiological analysis, the number of total coliforms present in this sample exceeds that recommended by the quality standards for drinking water in Benin. It's therefore important to disinfect this water by usual disinfection methods as chlorination based on calcium hypochlorite or sometimes with bleach, the active principle of which is sodium hypochlorite. The drinking water available in this locality has proven to be of good bacteriological quality due to the total absence of germs indicating faecal contamination in this water.
